

Project Iteration 5 Grading Rubric

1. Running the code.

	1	2	3	4
60%	Builds successfully but crashes and burns at some point.	Runs, but the scheduler doesn't appear to be doing anything (i.e., all the drones get dispatched to a zone). Timing isn't realistic at all (i.e., drones don't take time to move between zones).	Runs correctly with all 10 drones running in a reasonable fashion (i.e., the scheduler is doing something). Does not include any error scenarios such as stuck between zones, stuck door. (deduct 0.5 if no output showing the state of the system – an event log does not count). Cannot handle drone overflow.	Code runs flawlessly and handles demonstrably handles errors such as faulty doors and getting stuck between zones. Includes some sort of output (other than print statements of an event log) showing the position of the drone (deduct 0.5 GUI is missing). Can handle the case where there are more tasks assigned to the drone it can handle.

2. An estimate of the time it takes the system to handle the input file. This should be an estimate on the length of time it takes to process all of the passengers on the supplied data file. This data file will overload arrivals – this should be handled properly!

3.3	1	2	3	4
20%	Wall clock time only. One run, little or not explanation of the measurement process.	Code instrumented and more than one run conducted to find the mean value.	Code instrumented and more than one run conducted to find the mean value. Confidence intervals calculated showing that mean is actually a reasonable value.	Item 3 plus an explanation as to where the instrumentation was added and what the values returned mean. If the mean time per event was derived, rather than measured, an explanation of how and why. (i.e., timed 1000 events, then divided to find value - insufficient clock resolution).
